

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

INTRODUCTION

THESE time savers consist of the author's "Hydraulic Scales," from which the dimensions of pipes, drains and sewers can be easily and accurately ascertained, and his "Rapid Earthwork Calculation," from which the quantity of earthwork required in a bank or cut can be quickly calculated to, if necessary, the nearest inch of its depth,—strongly bound together into one convenient-sized manual.

PREFACE

THE accompanying Scales are taken from the Author's 'Water Supply and Drainage Systematised and Simplified,' in which work their construction is fully explained.

The dimensions, to the nearest inch, of pipes, of half-pipes, and of any design of drain or sewer in which a semicircle or circle can be inscribed, can be ascertained from them, adopting at will any desired coefficient.

Their issue in a handy setting will, it is hoped, recommend itself to the practical engineer.

C. E. H.

London, April 1914.

HYDRAULIC SCALES

SCALES HOW USED

The use of the scales in ascertaining the diameters of pipes and of half-pipes is simple and direct. Thus, if S 'the slope in the water surface' or 'the hydraulic gradient' of a pipe $\left(\frac{H}{L}\right) = \frac{I}{1600}$ and the required discharge is 20 gallons per minute (galmins = G), the value of $\frac{L}{H}G^2$ will be $1600 \times 20^2 = 640,000$, and the required diameter in inches (d) of a clean pipe will from the small inset scale be 4 in.

For Kutter's n = 0.013 it will be $4 + \frac{3}{4} = 4\frac{3}{4}$ in., and for an incrusted pipe it will be $4 + 1\frac{1}{4} = 5\frac{1}{4}$ in.

If, S being the same, the required discharge is 20 cubic ft. per second (cusecs = F) the value of $\frac{L}{H}$ F² will be also 640,000, and the exact required diameter (d) of a clean pipe (Prof. Unwin's coefficients) will, from the main scale, be 38 in.; and, using the accompanying book-mark—

For Kutter's
$$n = 0.013$$
 it will be $38 + 1 = 39$ in.
,, ,, $n = 0.010$,, ,, ,, $38 - 3 = 35$ in.
,, an incrusted pipe ,, ,, ,, $38 + 6 = 44$ in.

and so on.

To ascertain the diameter of a half-pipe to give, with a slope in the water surface of 1 in 1600, a discharge of 20 cusecs we should have to take 4 times the value of $\frac{L}{H}F^{a}$ or 640,000 \times 4 = 2,560,000, whence from the main scale d for a clean half-pipe = 49 in.

For Kutter's
$$n = 0.013$$
, $d = 49 + 1 = 50$ in.
,, , $n = 0.010$, $d = 49 - 4 = 45$ in.

The scales can moreover be further used for ascertaining the dimensions of any type of drain or sewer the area of which can be ascertained in terms of the diameter of a circle or semicircle inscribed in the drain design.

Their use for this purpose is based on the following considerations.

For any drain, from well-known formulæ-

$$F = A v$$
 . . . (i)

when A is the water area in square feet, and
 v is the velocity in feet per second;
also—

$$v = C \sqrt{R} \sqrt{S}$$
 . . (ii)

where R the hydraulic mean depth or $\frac{\text{water area}}{\text{wetted perimeter}} = \frac{A}{P}$ and

$$C = \sqrt{\frac{2g}{m}} = \sqrt{\frac{64.4}{m}}$$

m being a coefficient of flow, the value of which depends almost entirely on R and the character of the interior surface of the drain; therefore the value of $C \checkmark R$ for any given drain will, to all intents and purposes, be a constant and the velocity in the drain vary almost entirely with the slope of its water surface.

If now the hydraulic mean depth of the drain is the

as the hydraulic mean radius of the inscribed circle or
e II. drain (Plate II.), the

ope of the water surface a pipe or half-pipe with er slope.

owing through the area of scribed circle or semicircle a comparison of the area semicircle with the area of

y be designated 'the disnd denoted by r', the scharge being ascertained value of $\frac{L}{H}(Fr')^{3}$.

1 (Plate I.), the value of R R for the inscribed circle or 2 case, the velocity in the ld, under similar conditions, we with the diameter of the 12 allowance will have to be

ity in any drain or pipe will value of C \sqrt{R} , ascertained or hydraulic mean radius, er surface be very approxi= 0.013 from the following

$$\frac{.82 \times R}{R + 0.56}$$

values are: for drain $C \checkmark R = 130.5$, for semicircle $C \checkmark R = 116.6$; and with D = 9, $C \checkmark R$ for the drain = 221, and for the semicircle $C \checkmark R = 199$; whence the increased velocity in the drain will respectively be as 1.13 to 1, 1.12 to 1, and 1.11 to 1, or a mean of 112 to 100, and the value of r' will = $\frac{0.3927 D^2}{0.700 D^2} \times \frac{100}{112} = 0.50$.

Ascertained from a reduction coefficient so obtained the value of d for the inscribed semicircle in a Type I. drain will be slightly larger than it should be, as the values of d so obtained are based on the values of $\frac{L}{H}F^2$ calculated for $R = 0.250 \, \text{D}$. An error on the right side.

Thus for an unplastered masonry or concrete drain of Type I. to give a discharge of 20 cusecs with a slope in the water surface of I in 1600 we have for a semicircle—

$$\frac{4L}{H} (Fr')^2 = 4 \times 1600 \times (20 \times 0.5)^2 = 640,000$$

whence from the main scale d = 38 + 1 = 39 in. Therefore $A = 0.700 \times 39^3 = 1064.7$ square in. or 7.4 square ft. Also $C\sqrt{R} = \frac{182 \times 0.96}{0.98 + 0.56} = 113.5$, whence with S = 1 in 1600 the velocity in the drain $= \frac{113.5}{\sqrt{1600}} = 2.84$ ft. per second.

The discharging capacity of the drain is thus $7.4 \times 2.84 =$ 21 cusecs, instead of 20 cusecs.

The exact dimensions of the drain can be more nearly ascertained from the values of r' ascertained from an inscribed circle as shown in the full Type A drain section, side slopes I to $2\frac{3}{4}$, illustrated in Plate IV.

Thus to begin with, from Table I. (opposite page) 20 \times 0.15 = 3 and 1600 \times 3² = 14,400; therefore d for an unplastered drain = 18 + 1 or 19 in., whence half the depth of

the drain $\delta = I$ ft. 7 in. and A the water area of a full drain, 2.88^2 , = 7.1 square ft. Also as $C\sqrt{R} = \frac{182 \times 0.931}{0.96 + 0.56}$ = III.5, $v = \frac{III.5}{40} = 2.79$ ft. per second, and F therefore = $7.1 \times 2.79 = 19.80$ cusecs.

For a drain in earth a Type II. drain would be usually adopted.

For a drain with side slopes of I to I, 20 × 0.859 = say I7 and $4 \times 1600 \times 17^{2} = 1.849,600$, therefore for Kutter's n = 0.025, d = 46 + 17 = 63 in. = 5.25 ft., whence $A = 1.83 \times \left(\frac{5.25}{2}\right)^{2} = 12.62$ square ft. and $R = \frac{5.25}{4} = 1.31$.

The values of $C \sqrt{R}$ for Kutter's n = 0.025 can be very approximately ascertained for any slope in the water surface from the formula—

$$C\sqrt{R} = \frac{117 \times R}{\sqrt{R + 110}} . \quad (iv)$$

In the present case therefore-

$$C \sqrt{R} = \frac{I \cdot I \cdot J}{I \cdot I \cdot J} = 68$$

and $v = \frac{68}{40} = 1.7$ ft. per second. F therefore = 12.62 \times 1.7 = 21.45 cusecs.

Occasionally a shallower drain than a Type II. drain may be advisable, and the dimensions of a Type B drain (Plate IV.) can be ascertained from the values of r' given in Table I.

Thus for a drain with $b=4\delta$ and side slopes of 1 to 1, $F \times r' = 20 \times 0.073 = \text{say 1.5}$

whence
$$1600 \times 1.5^2 = 3600$$

and d for Kutter's n = 0.025 = 14 + 6 = 20 in.

Whence
$$A = 5\delta^2 = 5 \times \left(\frac{20}{12}\right)^2 = 13.8 \text{ square ft.}$$

and $R = 0.73 \delta = 0.73 \times 1.67 = 1.22$
also $C\sqrt{R} = \frac{117 \times 1.22}{1.1 + 1.1} = \frac{142.7}{2.2} = 64.8$
therefore $v = \frac{64.8}{40} = 1.62 \text{ ft. per second}$
and $F = Av = 13.8 \times 1.62 = 22.36 \text{ cusecs.}$

To ascertain the dimensions of an egg-shaped sewer (Plate III.) to discharge 20 cusecs with a slope in the water surface of I in 1600 we have $20 \times 0.62 = \text{say 12.5}$, and as for a circle $1600 \times 12.5^2 = 250,000$, therefore d for an unplastered masonry or concrete sewer = 3I + I = 32 in.: whence $A = I.149 \times \left(\frac{3^2}{12}\right) = 8.2$ square ft., and as $R = \frac{3^2}{12} \times 0.290 = 0.77$, $C \checkmark R = \frac{182 \times 0.77}{0.88 + 0.56} = 97.4$ and $v = \frac{97.4}{40} = 2.44$ ft. per second. F therefore $= 8.2 \times 2.44 = 20$ cusecs.

It will be seen from the above examples that the scales can be used for quickly and accurately ascertaining the dimensions of a number of useful types of drains and sewers to suit any required discharge and any slope in the water surface, adopting at will any desired coefficient. The velocity need not be worked out in each case except as an additional precaution to ensure that there is no mistake in the ascertained dimensions. It is, however, essential that there should be no great error in the ascertained values of $\frac{L}{H}G^2$ or $\frac{L}{H}F^2$. These can be checked from Table II. in the following manner:—

With $S=\frac{1}{1532}$ and F=13 cusecs take and add from the horizontal column opposite required discharge = 13—

1000 times the figure in the vertical col. I = 169,000100 ,, ,, ,, 5 = 84,500 10 ,, ,, ,, 3 = 5,070 1 ,, ,, ,, 2 = 338 and the value of 1532×13^2 will = 258,908

With F = 1.3 the value of $\frac{L}{H}F^2$ will obviously be 2589.08, and with F = 130 it will be 25,890,800.

With F = 13.5 a mean may be taken between the ascertained values for F = 13 and F = 14.

PREFACE

This small work embodies improvements in earthwork calculation suggested by a careful reconsideration of the author's "Practical Earthwork Tables," these Tables, as well as their application, being considerably simplified yet left sufficiently full to allow of correct results being arrived at under all the conditions likely to be met with in actual practice.

With so many Tables already in existence for a similar purpose new ones may at first sight appear unnecessary and superfluous; actual trial will, however, prove that earthwork quantities can be from them ascertained, as within explained, more quickly and with less labour than in any other way.

	THE TABLES				29

CHAPTER I

INTRODUCTORY

THE usual procedure for ascertaining the amount of earthwork likely to be needed in an embankment or in a cutting is—

(a) First of all to prepare a longitudinal section along the centre line of the proposed bank or cut from levels taken at, as far as possible, regular intervals along this line, and also to prepare cross-sections at right angles to the centre line at the points at which the levels are taken; (b) to then determine from the plotted cross-sections the areas of embankment and cutting required at each such station; and (c) finally to calculate from the areas so obtained the contents of the bank or cut from the

prismoidal formula or from the mean areas of adjacent cross-sections.

The above procedure necessitates a good deal of work in the preparation of the cross-sections and also in the numerical calculations necessary before and after the areas of bank and cutting at each station can be and have been ascertained. The accompanying Tables and connected formulæ will be found to be of material assistance in the reduction of such work.

Where the ground at right angles to the centre line is level or has a uniform cross slope the preparation of any cross-sections is by their use rendered unnecessary.

Where the cross slopes at the selected points are not uniform the preparation of the cross-sections can be also generally avoided by the adoption of an average cross slope at each station, or is at any rate much simplified.

The Tables are, however, especially applicable to the rapid and direct calculation, by the system later on explained, of the cubic contents of long embankments and cuttings carried over or through ground which rises and falls to a considerable extent.

This method of ascertaining the contents of a bank or of a cut further allows of an easy check being kept on the progress of work when such bank comes to be thrown up or such cutting made, an additional advantage in its favour.

For rapidly ascertaining the relative cost of trial lines it will be found also most useful.

CHAPTER II

TABLES, HOW FRAMED

The usual cross-sections of embankments and cuttings on level ground (area in square feet $\stackrel{\cdot}{=}$ A) are illustrated in Fig. (i.)—

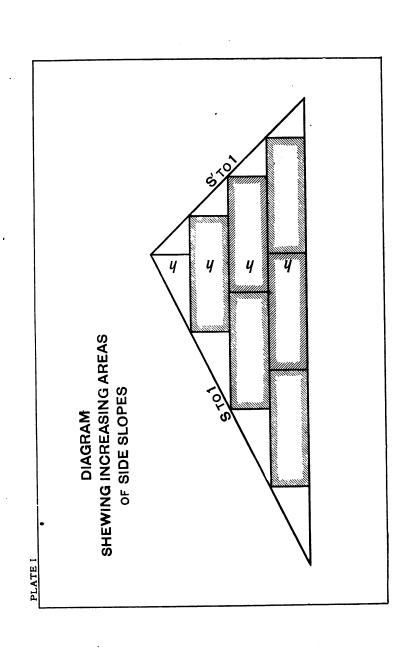

where-

- (b) is, in feet, the top width of a bank or the bed width of a cut;
- (d) is, in feet, the height of a bank or the depth of a cut; and
- S, S', are the horizontal values to 1 of the side slopes generally denoted as $\frac{1}{2}$ to 1, 1 to 1, 2 to 1, and so on.

If the central area $b \times d$ is eliminated the values of the remaining triangular end areas will depend directly on the values of S and S'.

Thus for any depth h the combined area of

the two end areas will (see Plate I.) be equal to—

$$\frac{1}{2}h(Sh + S'h) \text{ or } \frac{1}{2}h^2(S + S')$$
 . (i.)

Their area for an additional depth h will be—

$$\frac{1}{2}h^2(S + S') + h^2(S + S')$$
. . (ii.)

Equation (ii.) can, however, be written—

$$2h^2(S + S') - \frac{1}{2}h^2(S + S')$$
 . . (iii.)

hence the area (A^n) of an nth layer can be obtained from the equation—

$$A^n = nh^2(S + S') - \frac{1}{2}h^2(S + S')$$
 . (iv.)

The increase in area for each layer will from equation (ii.) obviously be—

Difference =
$$h^2(8 + S')$$
 . . . (v.)

The Tables at the end of work, which can be easily extended, have been prepared from the above formulæ with h=1 foot, and are applicable to banks or cuttings of a total height or depth of 30 feet, with side slopes varying from $\frac{1}{2}$ to 1 to 4 to 1 on both sides to $\frac{1}{2}$ to 1 on one side and $7\frac{1}{2}$ to 1 on the other one.

The combined area (A¹) of the end areas of a layer *i* inches deep immediately below a *n*th one foot layer can be further ascertained from the formula—

$$A^{1} = Difference \times \frac{i}{12} \left\{ n + \frac{i}{24} \right\}.$$
 (vi.)

whence for a 6-inch layer—

$$A^{1} = \text{Diff.} \times \left(\frac{n}{2} + 125\right)$$
. (vii.

The total area (A²) of this half-foot layer being thus—

$$A^2 = \frac{1}{2}b + A^1$$
 . . . (viii.)

For a 3-inch layer—

$$A^{1} = \text{Diff.} \times (\frac{n}{4} + .03125)$$
 . (ix.)

and for a 9-inch layer-

$$A^{1} = Diff. \times (\frac{3n}{4} + 1.28125)$$
 . (x.)

CHAPTER III

APPLICATION OF THE TABLES

The Tables and connected formulæ can, in the first place, be used for ascertaining the area of the cross-section of a bank or of a cut when the cross slope is level and d is known to the nearest inch.

Take the case of a bank 12 ft. high with a top width of 20 ft. and side slopes of $1\frac{1}{2}$ to 1 on both sides.

Then $S + S' = 1\frac{1}{2} + 1\frac{1}{2} = 3$, and the area of the cross-section of the bank will be, as d = 12 ft. and b = 20 ft.—

Area of central portion
$$b \times d$$
 = 240 sq. ft.

End areas combined for
$$d = 12$$
 from Tables $= 216$,

Or the total area of the bank (A)
$$= 456$$

For such a bank 12 ft. 6 in. high the area of the combined end areas of the lowest 6 in. would from equation (vii.) as Diff. = 3, be—

$$A^{1} = 3(\frac{12}{2} + .125) = 18.375 \text{ sq. ft.}$$

and the area of the entire 6-in. layer-

$$A^2 = \frac{20}{2} + 18.375 = 28.375 \text{ sq. ft.}$$

the total area of the cross-section of the $12\frac{1}{2}$ ft. bank being thus—

$$A = 456 + 28.375 = 484.375$$
 sq. ft.

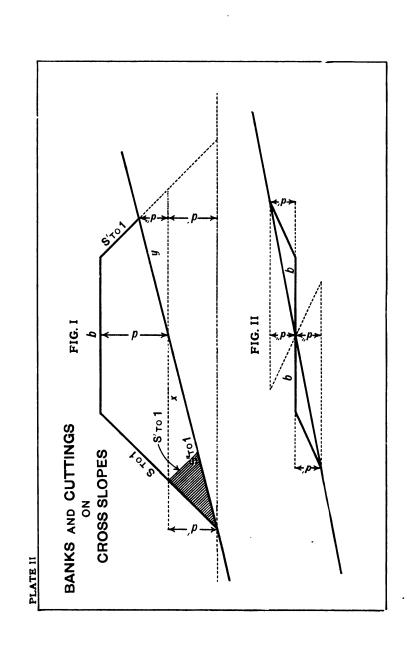

When the ground has a cross slope S" to 1 as shown in Fig. I., Plate II., the area of bank needed could clearly be approximately ascertained from the Tables and formula (vi.) by calculating to the nearest inch the values of d' and d'' from the following formulæ—

$$d'(S'' - S) = \frac{1}{2}b + Sd$$
 . (xi.)

and

$$d''(S'' + S') = \frac{1}{2}b + S'd$$
 . (xii.)

The area of the cross-section can, however, be more easily ascertained (as the area of the triangle x is equal to that of the triangle y) by adding the area of the shaded portion in the lower left-hand corner of Fig. I. to the area of a bank on level

17

ground. This shaded area can be accurately calculated from the following formula—

$$A^3 = \frac{1}{2}d'^2 \left\{ (S + S') - \frac{(S + S')^2}{S'' + S'} \right\} . (xiii.)$$

which reduces, when as is usually the case S' = S, to

$$A^4 = d'^2 (S - \frac{2S^2}{S'' + S})$$
 . (xiv.)

For the 12-ft. bank above considered, if the cross slope S'' to 1 = 4 to 1, we have from formula (xi.)—

$$d'(4 - 1\frac{1}{2}) = \frac{1}{2} \times 20 + 1\frac{1}{2} \times 12$$

whence $d' = 11.2$ ft.

therefore from formula (xiv.)-

$$A^{4}=11\cdot2^{2}\left\{1\frac{1}{2}-\frac{2\times\left(\frac{3}{2}\right)^{2}}{4+1\frac{1}{2}}\right\}=125\cdot44\times\cdot68=85\cdot3\text{ sq. ft.}$$

and the area of the whole bank will be

$$A + A' = 456 + 85.3 = 541.3$$
 sq. ft.

which careful calculation will show is the correct area.

We thus have an easy and accurate method

of determining the cross-sectional area of a bank or of a cutting (a cutting being merely a bank turned upside down) on a cross slope, whatever this cross slope may be.

When such areas are equally partly in bank and partly in cutting, as shown in Fig. II., Plate II., and the slide slopes are similar

$$d'(S'' - S \text{ or } S') = b \qquad (xv.)$$

also $A^{5} = \frac{b^{2}}{2(S'' - S \text{ or } S')} \quad . \quad (xvi.)$

Thus with b = 10, S = 2, and S'' = 4—

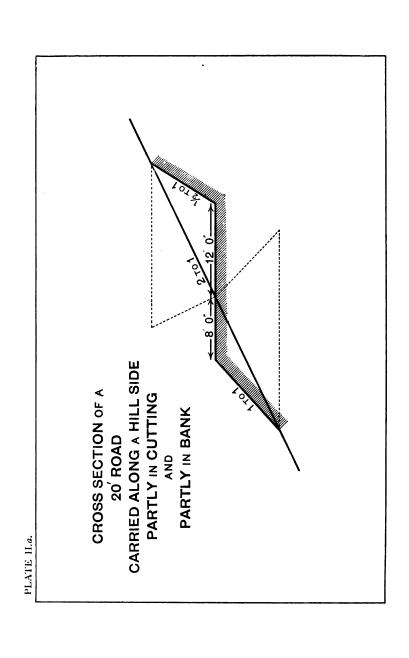

$$A^5 = \frac{10^2}{2(4-2)} = \frac{100}{4} = 25 \text{ sq. ft.}$$

When the areas are not equal, or the side slopes are dissimilar as illustrated in Plate II.a, the area of cutting in such case will similarly be

$$A^5 = \frac{12^2}{2(2 - \frac{1}{2})} = \frac{144}{3} = 48 \text{ sq. ft.}$$

and the area of embankment will be

$$A^5 = \frac{8^2}{2(2-1)} = \frac{64}{2} = 32 \text{ sq. ft.}$$

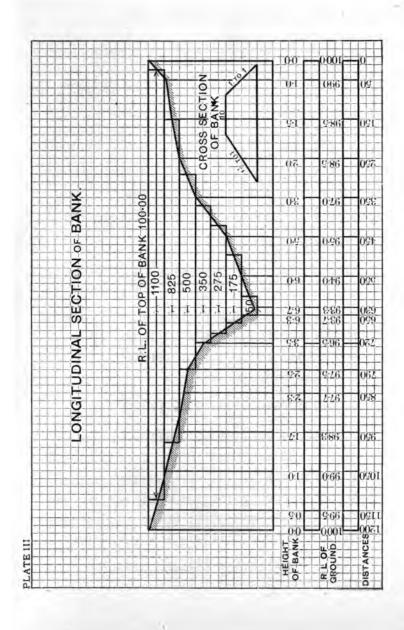

The correct cross-sectional areas of banks and cuttings having side slopes ordinarily used, can thus, without the preparation of cross sections, be quickly and accurately ascertained from the Tables and associated formulæ for both level ground and ground with a cross slope.

The Tables are, however, of special assistance in the calculation, by the method explained below, of the cubic contents of long lines of single or connected embankments and cuttings carried over or through ground which rises and falls to a considerable extent.

Consider Plate III. Here we have to ascertain the contents of a single bank with a top width of 10 ft. and side slopes of $1\frac{1}{2}$ to 1 on one side, and 1 to 1 on the other, carried, on the level, across a valley 1200 ft. wide, and having a maximum depth of 6.7 ft., or say 7 ft.

By drawing lines 1 ft. apart parallel to the formation level (top of bank), and ascertaining the length of each 1 ft. layer, the contents of the bank can be ascertained from the Tables, using the column for $S + S' = 1\frac{1}{2} + 1 = 2\frac{1}{2}$, in the following manner:—

Area of each 1 ft. layer in square feet.	Length of each 1 ft. layer in feet.	Contents of each 1 ft. layer in cubic feet.	Total contents at specified depths in cubic feet.	
1st layer 10+ 1·25 = 11·25 2nd , 10+ 3·75 = 13·75 3rd , 10+ 6·25 = 16·25 4th , 10+ 8·75 = 18·75 5th , 10+11·25 = 21·25 6th , 10+13·75 = 23·75 7th , 10+16·25 = 26·25 A = 10×7 + 61·25 = 131·25		12,375·00 11,343·75 8,125·00 6,562·50 5,843·75 4,156·25 1,312·50	12,375·00 23,718·75 31,843·75 38,406·25 44,250·00 48,406·25 49,718·75	

Thus the total contents of the bank = 49,718.75 cub. ft.

If when the bank is being actually thrown up the completed portion is 3 ft. below formation level, the amount of earthwork put into the bank will clearly be

49,718.75 - 31,843.75 = 17,875 cub. ft.

If the ground over which the bank is carried has a considerable cross slope, the quantity of earthwork needed will be increased, and the amount of such extra earthwork can be very approximately ascertained by calculating from formulæ (xi.) and (xiii.) the increase in the area

¹ For a 9-inch layer A^2 would = 21.33 sq. ft.

of the cross-section of the bank at its greatest depth, and then ascertaining a mean of this area for the entire bank in the manner illustrated in the following example.

Such mean area multiplied by the total length of the bank will very nearly give the quantity of the extra filling needed.

Thus if, in the case of the bank at present under consideration, the cross slope of the ground over which it is carried is 5 to 1 towards d', we have from formula (xi.)—

$$d'(5-1\frac{1}{2}) = \frac{1}{2} \times 10 + 1\frac{1}{2} \times 7$$
 whence
$$d' = 4.43 \text{ ft.}$$

also from formula (xiii.)—

$$A^{3} = \frac{1}{2} \times 4.43^{2} \left\{ 2\frac{1}{2} - \frac{\left(2\frac{1}{2}\right)^{2}}{5+1} \right\}$$

$$= 9.8 \times 1.46$$

$$= 14.3 \text{ sq. ft.}$$

As the amount of earthwork in the bank with the cross slope level is 49,718.75 cub. ft. and the bank's length is 1200 ft., its mean area is $\frac{49,718.75}{1200} = 41.4$ sq. ft., or $\frac{41.4}{131.25}$

= 0.315 of the maximum area, the mean area for the additional earthwork will thus be say $14.3 \times 0.315 = 4.50$ sq. ft. Whence the amount of extra earthwork due to the bank being on a cross slope of 5 to 1, will be $4.50 \times 1200 = 5400$ cub. ft. The total amount of filling needed for the entire bank being thus about 55,120 cub. ft.

The method above illustrated can be applied to the calculation of the quantities of earthwork in a long series of connected banks and cuttings carried over or through uneven ground as illustrated in Plate IV.; the longer such a series of connected banks and cuttings, the smaller the relative amount of work necessary to ascertain the amount of earthwork required throughout.

The quantities of embankment and cutting needed under the conditions indicated on Plate IV. are worked out from the Tables and associated formulæ in the following statement, which gives, in a tabulated form, the contents of a connected series of banks and cuts having a total length of no less than 6000 ft.

PLATE IV

Total as	nount of e	arthwork	1,170,395 c	oub ft
Total al	mount of 6	COLULIWOUR	1,110,000	uv. It.

To obtain the same result in the ordinary way would, with the stations at which cross-sections would be needed 100 ft. apart, have necessitated levels being taken for the preparation of cross-sections at no less than 60 stations, the calculation of the areas of the bank and cutting needed at each station, and finally the calculation from the areas so ascertained of the cubic contents of the banks and cutting by the prismoidal formula or other similar process.

In the above calculations the cross slope of the ground has been assumed to be negligible. Suppose, however, that it cannot be ignored, and is for the main bank 10 to 1. Then, as the greatest depth of the bank is 14 ft., we have from formula (xi.)—

$$d'(10 - 1\frac{1}{2}) = \frac{1}{2} \times 16 + 1\frac{1}{2} \times 14$$

and therefore $d' = 3.4$ ft.

Also from formula (xiv.)-

$$A^{4} = 3 \cdot 4^{2} \left(1\frac{1}{2} - \frac{2 \times \frac{9}{4}}{10 + 1\frac{1}{2}}\right)$$

= 11 \cdot 56 \times 1 \cdot 1 = 12 \cdot 716 \text{ sq. ft.}

Now as the contents of the bank are 1,100,620

cub. ft., and its length 4200 ft., its mean area is thus about 262 sq. ft., or $\frac{262}{518}$ = say ·51 of the maximum cross-section of the bank. The mean area of the increase in earthwork will thus be $12 \cdot 716 \times 51 = 6 \cdot 485$ sq. ft., and the amount of extra earthwork needed due to the bank being carried over ground with a cross slope of 10 to 1, say $6 \cdot 5 \times 4200 = 27,300$ cub. ft., or an increase of only 0.025 of the total contents of the bank with the cross slope of the ground level. Unless, therefore, the cross slope is excessive, it need not generally be taken into consideration.

With the longitudinal section plotted to a scale of 100 ft. to the inch instead of 1000 ft. (approximately), the mean lengths of each 1 ft. layer could be more exactly ascertained than is the case in the above example, and the required amount of earthwork more accurately calculated.

It will, therefore, it is hoped, be clear that, by the method above outlined, the contents of the embankment and cutting required for a drain, canal, dam, road or railway can be easily and accurately ascertained by practically one set of calculations, whatever the length of either may be.

Table giving the End Areas in Square Feet of Bank and Cut Sections for their Side Slopes S and S' to 1 added together.
